

ORIGINAL

INEEL PUBLIC MEETING ON PROPOSED CLEANUP PLAN
FOR WASTE AREA GROUP 5
(POWER BURST FACILITY/AUXILIARY REACTOR AREA)

Taken at the Red Lion
Lewiston, Idaho
Wednesday, May 19, 1999 - 7:04 p.m.

A P P E A R A N C E S

ERIK SIMPSON, of Idaho National Engineering
and Environmental Laboratory.

SCOTT RENO, of the State of Idaho Department
of Health and Welfare, Division of Environmental
Quality.

RICK POETON, of the U.S. Environmental
Protection Agency.

KEVIN O'NEILL, U.S. Department of Energy

Reported by Jessica S. Berke, CSR, Freelance
Court Reporter and Notary Public, States of
Idaho and Washington, residing in Lewiston, Idaho.

1 WEDNESDAY, MAY 19, 1999 - 7:04 P.M.

2 MR. SIMPSON: Okay. I think we'll get
3 started. Welcome. I'm Erik Simpson. I'm the
4 Community Relations Plant Coordinator for the INEEL
5 Environmental Restoration Program. And I'll facilitate
6 tonight's meeting. Despite the light turnout, I think
7 I'll just keep the format the same just for the sake of
8 consistency.

9 We're here tonight to discuss the Waste Area
10 Group 5 Proposed Plan and the Remedial Investigation
11 and Feasibility Study. This is the sixth comprehensive
12 environmental investigation completed at the INEEL and
13 we have three more to go. The Waste Area Group 5
14 Proposed Plan follows the same format and style as the
15 Waste Area Group 1 Proposed Plan, which was released
16 last fall. And that document was developed with the
17 help of a Citizens Focus Group.

18 The Waste Area Group 5 Proposed Plan was
19 reviewed by our citizens advisory board in draft form.
20 And their comments and suggestions were incorporated
21 into the final version of this document. So really, a
22 lot of time has gone into this document, both with the
23 help of the Citizens Focus Group and the ER
24 sub-committee of the Citizens Advisory Board.

25 I'll just go quickly through the agenda, the

1 plans for tonight. We'll have the Waste Area Group 5
2 presentation and then we'll have a questions and
3 answers session following the presentation. And I just
4 should mention that if a question comes up during the
5 presentation, just go ahead and ask the presenter. And
6 then following the presentation we'll still have a Q
7 and A session. Following the questions and answers,
8 we'll have a short break and then we'll come back and
9 we'll have a formal public comment period, where your
10 comments will be entered into the record. And we have
11 a court reporter here tonight -- actually two court
12 reporters here tonight recording this meeting.

13 You can also submit your comments in writing.
14 And we have a postage paid comment form in the back of
15 the proposed plan. And then I also at the back table
16 have some comment forms also. Basically just jot down
17 your comments, fold that one-page sheet in the back,
18 and then put it in the mail. Also, for the first time,
19 citizens can submit their comments on the Proposed Plan
20 via the Internet on our EM website.

21 Also, if you don't mind, on the back of our
22 agenda we have an evaluation form and let us know if
23 the format of this meeting works for you or if you have
24 some other suggestions.

25 At this time I'll introduce the presenters.

1 Starting off will be Scott Reno. Scott is the Waste
2 Area Group 5 Project Manager for the State of Idaho
3 Department of Health and Welfare, Division of
4 Environmental Quality. And Scott will talk about -- he
5 will give an overview and he will talk about the
6 contaminant sources.

7 Next we have Rick Poeton with the
8 Environmental Protection Agency Region 10 in Seattle.
9 And Rick is here in place of Keith Rose. And Rick will
10 discuss the risk assessment process and the remedial
11 action objectives.

12 And then Kevin O'Neill. Kevin is the Project
13 Manager for the Department of Energy. And Kevin will
14 discuss the proposed remediation alternatives for the
15 contaminant sites and will provide a summary at the end
16 of the presentation.

17 So with that, I will turn it over to Scott.

18 MR. RENO: Thanks, Erik. No microphone
19 tonight? Everybody can hear me?

20 AUDIENCE MEMBER: It didn't work.

21 MR. RENO: If you can't hear me very well in
22 the back give me the volume up sign. Waste Area Group
23 5 is the Power Burst Facility/Auxiliary Reactor Area at
24 the INEEL. Please let me know if you need me to talk
25 louder. The INEEL itself, if you have never been down

1 there, is about thirty-two miles east -- or west of
2 Idaho Falls. And Waste Area Group 5 is located here in
3 the south central portion of the reservation.

4 The area consists of two operational areas.
5 The stet is the Power Burst Facility and it was the
6 location of the SPERT reactors, which were special
7 power excursion reactors tests. And the secondary to
8 the southeast was auxiliary reactor area. Also, you
9 may follow along if you have the handout that has --
10 this is the cover. I am using some figures rather than
11 the verbiage that's listed in those bullets there, but
12 you can follow along there if you would like.

13 In the north area there are a total of five
14 reactors that have operated there beginning in the '50s
15 and running into the present. There is actually one
16 reactor which is in standby mode, but still could be
17 made operational. And that is here at the power burst
18 reactor. And then the SPERT reactors, SPERTs 1, 2, 3
19 and 4 are no longer in service. SPERT 2 area is
20 Engineering Development Facility; SPERT 3 is the
21 current location of the Waste Experimental Reduction
22 Facility, which is an incinerator which is present on
23 the site.

24 And the fourth area is the Mixed Waste
25 Storage Facility, which is currently used for storage

1 of some mixed low level waste. Down here in the ARA
2 area was the facilities at ARA-I and II, which were
3 used to support operations for the SL-1 reactor, which
4 was the Stationary Low-Power Reactor. That was the
5 site of the accident in 1961. And I could discuss that
6 in a little bit more detail, if you would like, in a
7 moment. ARA-III housed the Army's gas-cooled reactor
8 experiment. And ARA-IV was the location of the nuclear
9 effects reactor and the Mobile Low-Power Reactor. All
10 of these facilities have been D and D, or
11 decontaminated, decommissioned, and dismantled. And
12 the only activity which remain are in a bunker at
13 ARA-IV where some conventional explosives testing
14 occurs.

15 In our IFS we investigated a total of
16 fifty-five sites, forty-eight of which were determined
17 to require no further action. There have been some
18 cleanup activities that have already occurred there in
19 the past. We cleaned up some contaminated sediments in
20 the evaporation pond for the PBF reactor which received
21 some cooling waters and some water softener
22 regeneration wastes. And it was contaminated with some
23 chromium and cesium-137. And we also removed the
24 contaminated sediments in the sump that fed that
25 evaporation pond.

1 We capped the Burial Ground proper for the
2 trenches and the pit were from the SL-1 accident, the
3 engineered barrier. We removed contents of our ARA-II
4 site, which we are going to take further on -- or are
5 proposing to take further action on in this Proposed
6 Plan and Removal Action -- in 1995 so we have
7 fifty-five gallons of sludge that they are maintaining
8 in the group compliant storage until disposition of
9 this proposed plan.

10 And then we have seven sites which we feel
11 require further action. First of these is located
12 south -- south of SPERT-II. And that is the PBF-16
13 pond. It receives water softener wastes from the
14 SPERT-II facility. And there is a small amount of
15 Mercury that is present near the outfall to that pond.
16 It's a shallow lined pond. We're estimating on the
17 order of five hundred cubic yards of soil will need to
18 be removed from this area.

19 AUDIENCE MEMBER: Question.

20 MR. RENO: Yes.

21 AUDIENCE MEMBER: Removed to where?

22 MR. RENO: We're proposed -- we'll discuss in
23 much greater detail the proposed remedial actions in
24 Kevin's portion of this. But we're looking at a
25 continuing approach. And the preference is for it to

1 go to the proposed soil repository. Okay.

2 AUDIENCE MEMBER: Then no subtitle C?

3 MR. RENO: Right. If there is one, decision
4 has not been made as of yet. Okay.

5 Second soil site -- second of our five soil
6 sites is the ARA-I Chemical Evaporation Pond. It
7 receives some wastes from the hot shops at the ARA-I
8 facility, and perhaps some chemical waste from a small
9 preparation lab that was present there. And we believe
10 there is on the order of up to twenty-four hundred
11 cubic yards of soil that is present there, which is
12 contaminated with Selenium and Thallium.

13 The third of our five soil sites is the
14 ARA-III Radioactive Leach Pond. This is a shallow and
15 natural depression that is west of the ARA-III
16 Facility. It may have received some cooling waters
17 associated with the gas cooled reactor experiment, or
18 perhaps some of the other operations that were ongoing
19 at that facility. There is on the order of ninety
20 cubic yards of sediments contaminated primarily with
21 cesium-137 and silver-108m that are present at that
22 site.

23 4 and 5 is some contamination which was
24 discovered fairly recently during the decontamination
25 decommissioning activities at the ARA-I Facility. When

1 they were removing one of the concrete floor slabs
2 there was some contaminated soil that was encountered
3 in the vicinity of some floor drains. We don't know
4 precisely how the contamination got there, but we're
5 assuming that on the order of seventy cubic yards of
6 soil contaminated with low level radionuclides are
7 present there.

8 Yes, Jack?

9 AUDIENCE MEMBER: What's the history of those
10 hot cells? What kind of work were they doing?

11 MR. RENO: Well, they were supporting
12 operations at SL-1. And I believe they had a metal
13 etching process that was there, I assume to examine
14 fuels. I don't have a detailed knowledge of the
15 history of that. I don't know if Jean --

16 MS. HOLDREN: Subsequent to the SL-1 accident
17 the facility was decontaminated and the hot cells were
18 then used to support whatever program when the INEEL
19 needed something done in a hot cell. So there were a
20 variety of activities at that facility.

21 AUDIENCE MEMBER: What kind of material would
22 they be handling? Fuel or --

23 MS. HOLDREN: No. There weren't any fuel
24 handling processes. They were usually things like
25 splitting samples, for example, soil samples,

1 subdividing.

2 AUDIENCE MEMBER: Splitting them?

3 MS. HOLDREN: Subdividing soil samples into
4 smaller components. That had to be done by remote
5 operations because of contamination. That's the type
6 of activities, as an example.

7 MR. RENO: Okay. Thank you. The last of
8 these five soil sites is remaining windblown
9 contamination associated with the SL-1 incident. This
10 is approximately a fifty-eight-acre area. We believe
11 most of the contamination that is present there was
12 generated as they were moving debris from the facility
13 to it's burial grounds in '62 to '63. The contaminant
14 of concern that is present here is cesium-137. And we
15 believe that most of it is confined to the upper four
16 inches of soils at this site. That area comprises on
17 the order forty-six thousand five hundred cubic yards
18 of material, and is far away the largest volume of
19 material that we're proposing to take action on.

20 MR. SIMPSON: Scott, do you want to touch
21 just a little bit on the accident itself, for those who
22 aren't familiar?

23 MR. RENO: Sure. On January 3rd of 1961, the
24 SL-1 reactor experienced a power excursion which heated
25 the cooling liquid around the reactor vessel and

1 resulted in a steam explosion that subsequently and
2 tragically killed the three operators that were on duty
3 that day. The reactor was intended for use by the
4 military. It was an experimental reactor to look at
5 potentially providing power at remote Arctic
6 installations. And it appears that one of the
7 operators inadvertently -- or who knows why -- removed
8 one of the control rods and resulted in an uncontrolled
9 chain reaction. The Atomic Energy Commission tore the
10 structure down. And the majority of those components
11 were addressed under previous record and decision at
12 present in that -- in the burial ground.

13 MR. SIMPSON: Thanks.

14 MR. RENO: Any questions about that? Looks
15 like most of you have some familiarity with the
16 incident.

17 AUDIENCE MEMBER: There was at the last
18 meeting of the INEEL sub-committee there was a
19 presentation by the CDC contractor about the
20 radioactivity that got dispersed. And it was kind of
21 curious, because there was two different versions of --
22 the cloud, according to one source, went in the
23 direction of American Falls in a southwestern
24 direction, where -- but all the sampling data --
25 environmental sampling data showed that the highest

1 concentrations were actually to the northeast, more
2 consistent with your ground contamination pattern.

3 MR. RENO: It's my understanding that when
4 the incident happened that the wind initially was
5 blowing to the northeast. And I know there is some,
6 you know, uncertainty in the records and some of the
7 accounts of this, but this is my understanding. Blew
8 shortly to the northeast and then came back down back
9 behind Big Southern Butte and then the wind shifted and
10 it blew the cloud off over the Mud Lake area. So
11 that's how I understand that it occurred. But I --
12 there may be some other accounts that are out there as
13 well. Thank you, Chuck.

14 Okay. The two remaining sites we are
15 proposing to take action at are tank sites, tank system
16 sites. The first of these is the ARA-16 mixed
17 low-level radionuclide tank. It's a one thousand
18 gallon stainless steel tank. It's in a vault back
19 behind the ARA-I Facility. There is approximately
20 twenty-nine gallons of sludge that's in the tank, and
21 up to a hundred gallons of other liquid that could be
22 associated with it.

23 We lowered a camera down into the tank a
24 couple years ago. It's in very good shape. You could
25 still read the grease pencil writings on the side of

1 the tank. There is no indication there has been leaks
2 from the tank itself.

3 However, in the vault soils we did detect
4 some Cesium contamination which was present at
5 concentrations that are generally consistent with the
6 rest of the Cesium contamination associated with the
7 SL-1 incident. There were not other constituents that
8 were associated with the tank contents in tank vault
9 soils. We don't believe that there has been a release
10 from the tank itself.

11 AUDIENCE MEMBER: How would you characterize
12 that waste?

13 MR. RENO: Mixed low-level radionuclide waste
14 with PCBs. And I believe -- you're probably interested
15 in whether or not it's transuranic. And I believe that
16 the concentrations of transuranics in that waste was in
17 the order of point four picocuries per gram. Do you
18 have some other data, Chuck?

19 AUDIENCE MEMBER: Yeah. In your -- the
20 reference, the final work plan -- I hope this isn't
21 going to be the first blind side.

22 MR. RENO: No, no, no. In fact, I --

23 AUDIENCE MEMBER: I did fax this yesterday to
24 Kathleen so that she could tell you. Here it is
25 characterized as TRU mixed waste.

1 AUDIENCE MEMBER: I can answer that.

2 AUDIENCE MEMBER: And back here the
3 concentration levels for the transuranics, if you
4 convert it to -- down to nanocuries, which were in the
5 definitions, it meets the -- more than meets the
6 definitions for TRU -- mixed TRU.

7 MR. RENO: For the record, the reference
8 cited is Final Work Plan for Waste Area Group 5,
9 Operable Unit 5-12, Investigation Feasibility Study.
10 And concentrations of alpha emitters referenced are
11 americium-241 at three point four five microcuries per
12 gram, plutonium-238 at zero point three three
13 microcuries per gram, and plutonium-239 at zero point
14 two nine microcuries per gram. Do you have --

15 AUDIENCE MEMBER: While we're on that, there
16 is also in there -- that section right when you were
17 reading it puts the volume at fifty-some-odd gallons --
18 fifty-five gallons -- fifty-four gallons something of
19 liquid and forty-three gallons of sludge. So there is
20 quite a big difference --

21 MR. RENO: Discrepancy?

22 AUDIENCE MEMBER: -- in the quantity.

23 MR. RENO: Okay. Thank you. Do you have
24 something you wanted to add to that?

25 AUDIENCE MEMBER: I just have a little

1 insight. My name is Frank Webber. And the insight
2 here is the work plan was what we developed to actually
3 sample the tank for the second time. The analytical
4 results that we found at the time, I believe as far as
5 transuranics, it was significantly less than a hundred
6 nanocuries per gram.

7 Do you have those exact numbers, Jean? Do
8 you remember?

9 MS. HOLDREN: No, I don't.

10 AUDIENCE MEMBER: The other thing I think
11 that should be pointed out is the volume itself seems
12 to -- depends on whether you're talking about the
13 sludge that's been estimated in the volume or the total
14 liquids and sludge volume. And that tends to make up
15 the discrepancy between the two.

16 AUDIENCE MEMBER: Well, it's broken down in
17 there as fifty-four gallons something of liquid and
18 forty-three gallons of sludge.

19 AUDIENCE MEMBER: Right. And again that
20 was --

21 AUDIENCE MEMBER: That is a copy of the Final
22 -- that is a copy of the Final Work Plan.

23 AUDIENCE MEMBER: Yeah. The Work Plan was
24 what we used to develop our sampling plan. The
25 analytical results are found in the RIFS as a result of

1 sampling based on this original knowledge. I don't
2 recall exactly what we knew about the ARA 16 Tank prior
3 to going into there. But we identified it as a data
4 gap, and that's why we needed a sample.

5 MR. RENO: There you go.

6 AUDIENCE MEMBER: Now those are in
7 picocuries.

8 AUDIENCE MEMBER: Here is the analytical
9 results that we found as a result of the sampling.

10 AUDIENCE MEMBER: I just gave you the
11 radionuclides there. There were others.

12 AUDIENCE MEMBER: I guess for the benefit of
13 everybody else here we can see at least what it says
14 here.

15 AUDIENCE MEMBER: Also collected a sample
16 several years ago. The lid was not sealed down tightly
17 and some rain water -- we think now -- got in also. So
18 it changed the volume.

19 MR. RENO: Okay. Well, we'll look into that,
20 Chuck. And I'll make sure that it's not transuranic
21 waste. I don't believe it is. But we'll clarify that.

22 MS. HOLDREN: No, it's not. It has
23 transuranic constituents. But by definition it is not
24 transuranic waste.

25 AUDIENCE MEMBER: The INEEL calls

1 transuranics, I believe, anything over -- was it fifty
2 nanocuries per gram? As I recall. And NRC recognizes
3 it as a hundred nanocuries per gram. I think that's
4 where the definition problem was is what INEEL decided
5 to call transuranics.

6 AUDIENCE MEMBER: Well, no. That sampling
7 was done in 1997.

8 AUDIENCE MEMBER: No. That was background
9 information used to develop --

10 AUDIENCE MEMBER: That's why we developed the
11 work plan and identified the data. That is the '97 --

12 AUDIENCE MEMBER: Well, okay. At any rate,
13 if you have only got two different data sets you're
14 obliged to provide some meaningful rationale as to why
15 you choose one over the other one, you know, that will
16 float, otherwise you've got to present them both. But
17 it is a crucial issue, obviously. And you just can't
18 say, well, we like this data set better than the other
19 data set because this way we don't have to meet such
20 more stringent regulatory requirements.

21 AUDIENCE MEMBER: We're confident in this
22 data set because it was subjected to rigorous data
23 quality requirements.

24 AUDIENCE MEMBER: Well, the first one was
25 too.

1 MR. RENO: We'll verify that, Chuck. But I
2 think from a regulatory standpoint, probably if we
3 treat this at the advanced mixed waste treatment
4 project, even if it's below TRU, the treatment
5 residuals probably need to be disposed of as
6 transuranic waste would be anyway. So --

7 AUDIENCE MEMBER: Well, I understand that.

8 MR. RENO: But we will verify that. It does
9 look like there is some discrepancies there.

10 AUDIENCE MEMBER: But there is two other
11 issues involved. Say, for instance, a member of the
12 public says, Why are you spending all this money on
13 this more involved process when you are just talking
14 about mixed low level waste? You know, so, you know,
15 go with this in situ vitrification or something like
16 that. You know, why spend all the extra money? But
17 the difference is that those Alternative 3s would not
18 meet the regulatory ARARS if it was mixed TRU.

19 And then there is another thing. Even with
20 the preferred alternative, inasmuch as you appear to be
21 making a commitment to have it treated at the advanced
22 mixed waste treatment plant, that, you know, there is
23 no sampling data to confirm your assumption that the
24 tank, after fifty years of having mixed transuranic
25 waste in it, is not itself mixed TRU. So, you know,

1 the alternative there as far as the physical tank
2 itself, you know, is still open to question.

3 AUDIENCE MEMBER: We agree with that. There
4 will have to be a hazardous waste determination
5 provided on that tank as well as the piping that goes
6 into it prior to remediation.

7 MR. RENO: Okay. Yep. Thank you, Chuck.
8 With that, I'm going to turn this over to Rick with the
9 EPA to discuss risk assessment process and results.

10 MR. POETON: The risk assessment consisted of
11 three major elements. First, identifying the
12 contaminants of concern; what contaminants are present
13 and the degree of toxicity or carcinogenicity with
14 respect to human health and the environment. The
15 second element is to identify exposure pathways;
16 pathways of concern, such as direct exposure from
17 radiation, soil and groundwater ingestion routes and
18 dermal contact, contact to the skin. And the third
19 piece is to identify human and ecological, that is
20 plant or animal, receptors that could be exposed to
21 contaminants at levels of concern.

22 The -- excuse me. I think I'm out of order
23 here. For the human health evaluation under super fund
24 criteria, the acceptable of cleanup risk range for risk
25 management decisions runs from about -- runs from one

1 in a million to one in ten thousand. And that is
2 excess lifetime cancer risk.

3 For noncarcinogenic effects, the measure is
4 the hazard index. And that indicates a potential for
5 adverse effects to the most sensitive individuals such
6 as children. Hazards indices below one are those
7 unlikely to cause adverse effects.

8 For the human health assessment we looked at
9 two risk scenarios: The Occupational Scenario
10 addressed exposure to a worker eight hours a day, two
11 hundred and fifty days a year for a working lifetime of
12 twenty-five years. In this case, we looked at both a
13 current worker, someone who would be working on the
14 site presently, and a worker a hundred years in the
15 future.

16 For the current worker there are
17 institutional controls in place currently that operate
18 to reduce that worker's exposure and risk. The primary
19 pathways of concern in both circumstances are external
20 exposure and dermal absorption.

21 For the hypothetical future residential
22 scenario, the exposure conditions assumed are exposure
23 twenty-four hours a day, three hundred fifty days a
24 year for thirty years. And the exposure would begin
25 with someone starting to live there a hundred years in

1 the future. Primary pathways of concern, again, are
2 external radiation exposure and dermal absorption.

3 In addition to human health, risk assessments
4 look at ecological risk. For the ecological receptor
5 scenarios we examined possible impacts to birds,
6 animals, plants, reptiles and insects. We evaluated
7 individual species of concern as well as groups of
8 species; screened contaminants based on site-specific
9 data as well as data collected from literature
10 searches. And the receptors were assumed to inhabit
11 the area one hundred percent of the time.

12 AUDIENCE MEMBER: Question.

13 MR. POETON: Yes?

14 AUDIENCE MEMBER: In terms of your exposure
15 scenarios, inasmuch as you're evaluating surface soil
16 contamination as one of your major remedial actions, I
17 mean, wouldn't the resuspension of those contaminants
18 into the air constitute a pretty significant risk from
19 an internal exposure to the lungs?

20 MR. POETON: I don't know if that was modeled
21 specifically in this case. But I think I can tell you
22 from my experience on other sites that where you have
23 superficial deposits of Cesium or other primary Gamma
24 emitters, the risk driver will be the external exposure
25 from the surface.

1 And you're right. There will be some
2 resuspension and trainament in the air, but the
3 inhalation risk is very small compared to the risk that
4 you get just by being exposed to the material that's
5 already on the ground from the external radiation. I
6 know that's the case with Radium and similar Gamma
7 rays.

8 AUDIENCE MEMBER: Because it's just more
9 surface area from the whole body as opposed to the
10 limited area in the lung?

11 MR. POETON: Well, first off, the
12 resuspension rates aren't -- even conservatively
13 modeled, aren't particularly large. Most material like
14 that generally weathers into the ground over a period
15 of time. And resuspension rates will decrease fairly
16 rapidly with age. But basically it's because the risks
17 from the external radiation are so large and so
18 constant in a situation where someone is living there
19 that they just dominate the risk situation. You can
20 certainly calculate an inhalation risk, but it's small
21 enough to be ignored in the uncertainty with the other
22 risks.

23 AUDIENCE MEMBER: Although, it was not
24 ignored in our risk assessment. We did evaluate
25 inhalation as an existing pathway for contaminants of

1 concern.

2 AUDIENCE MEMBER: Inhalation just doesn't
3 show up as an exposure pathway that requires
4 addressing.

5 MR. POETON: Continuing on ecological risk
6 assessment, the ecological receptors receive exposure
7 and dose from contaminated soil and ingestion of
8 contaminated plants and prey. The highest ecological
9 risk estimates turned out to be for insect-eating
10 mammals such as Merriam's shrew and the northern
11 grasshopper mouse; as well as for insect-eating birds
12 such as the ruby-crowned kinglet and the western
13 bluebird, which, by the way, is the Idaho state bird.

14 AUDIENCE MEMBER: Actually, the mountain
15 bluebird.

16 MR. POETON: My mistake.

17 AUDIENCE MEMBER: My mistake.

18 MR. POETON: And the hazard quotient, the
19 ratio of potential dose to a toxicity reference value
20 is the indicator used to assess potential risk to
21 ecological receptors.

22 Looking now at the contaminants of concern
23 for the different cites for ARA-I, a Chemical
24 Evaporation Pond, the contaminants of concern were
25 selenium and thallium. Those represent primarily

1 ecological risks.

2 For ARA-III, the Radioactive Leach Pond, the
3 contaminants include cesium-137 and silver-108
4 metastable, which are radioactive contaminants
5 associated with human health risk, as well as
6 contaminants of concern, mercury, selenium and copper,
7 primarily ecological risk concerns.

8 Contaminated soils in ARA-I and II, the risk
9 concern is cesium-137 from a human health perspective.

10 For the ARA-I soil beneath the hot cells, the
11 issues are cesium-137, radium 226 and arsenic for human
12 health, as well as copper and lead for ecological.

13 At the SPERT-II Leach Pond Mercury is of
14 concern for ecological risk.

15 At the ARA-I Sanitary Waste System,
16 radionuclides cesium-137, radium 226 and uranium 235
17 and 238 are of concern for human health.

18 And finally, at the tank site, the ARA-I
19 Radionuclide Tank Site is cesium-137 of human health
20 concern.

21 Looking now at the risk assessment results.
22 Again, a couple of different features and current
23 scenarios addressed both the residential scenario in
24 the future, occupational scenarios, both current and in
25 the future, show risks exceeding the one in ten

1 thousand excess lifetime cancer risk criterion for
2 cleanup and action under Superfund, and in some cases
3 exceeding the hazard quotient cleanup criterion of ten
4 in this case for ecological risk.

5 AUDIENCE MEMBER: Let me point something out,
6 Rick. The risk estimate that is presented for the
7 ARA-16 Tank there is for the vault soils, not for the
8 tank contents itself. No risk is determined for the
9 waste because it had not yet been released into the
10 environment. We're taking action mitigating potential
11 release of the waste.

12 MR. POETON: Remedial action objectives for
13 those sites requiring action would be to inhibit direct
14 exposure to contaminants resulting in excess cancer
15 risk of one in ten thousands to workers or future
16 residents; to inhibit dermal absorption of any
17 contaminant of concern that would result in a hazard
18 index of two or greater for workers of future
19 residents; prevent the release of, and human and
20 ecological exposure to, ARA-16 tank contents; and
21 inhibit ecological receptor exposures to contaminated
22 soil with concentrations greater than or equal to ten
23 times background values, and that result in a hazard
24 quotient greater than or equal to ten.

25 The evaluation criteria for the remedial

1 alternatives are the standard nine criteria under the
2 Superfund requirements. The first two being the
3 threshold, must meet criteria of protecting the human
4 health and environment and complying with applicable or
5 relevant and appropriate laws and requirements.

6 The next five are the balancing criteria that
7 are used to weigh the various options against one
8 another, including long-term effectiveness, reduction
9 of toxicity, mobility, or volume through treatment,
10 short-term effectiveness, ease of implementation and
11 cost.

12 And finally among the nine criteria are the
13 modifying criteria of state acceptance and public
14 acceptance.

15 Any other questions?

16 Next up is proposed alternatives, Kevin
17 O'Neill.

18 Thank you.

19 MR. O'NEILL: The soil sites were all grouped
20 into one set of alternative evaluations. As a
21 standard, we look at no action -- the no action
22 alternative to baseline our other alternatives against.

23 The -- as Rick pointed out, the threshold
24 criteria are must meet criteria. And no action does
25 not meet that. Again, however, we do evaluate against

1 it.

2 The limited action criteria basically means
3 continuing the institutional controls that currently
4 are in place, including worker protection procedures
5 and environmental monitoring.

6 That also, for the three different actions
7 we're talk about tonight, is not suitable, does not
8 meet the threshold and was not evaluated further in the
9 proposed plan. The next two are Alternatives 3a and b,
10 excavate, consolidate and containment with a native
11 soil cover. That also was determined not to be
12 protected, because our baseline assumption is that
13 after a hundred years we can no longer guarantee
14 institutional control. And the contaminants that would
15 be buried under that cover are long-lived, and there is
16 no assurance that the cover would not erode away.

17 The next alternative is basically the same,
18 except with an engineered barrier that would ensure
19 that ecological receptors and humans were not able to
20 intrude into the waste and would be protected from
21 contact with it. That containment would be erected at
22 Waste Area Group 5.

23 The next four are all essentially removed and
24 dispose. The differences being removed and dispose --
25 removal process through a soil sorting technology

1 called segmented gate and dispose on site or dispose
2 off site.

3 Our preferred alternative is that we would
4 remove the soil, process it through a soil sorter,
5 provided that the technology is effective, and dispose
6 on site at a suitable designed soil repository.

7 AUDIENCE MEMBER: Question.

8 MR. O'NEILL: Sure.

9 AUDIENCE MEMBER: In terms of the excavation,
10 the two different excavation options, if it's mixed low
11 level waste, which it is, as far as I can tell --

12 MR. O'NEILL: Okay. Let me --

13 AUDIENCE MEMBER: -- that wouldn't meet any
14 -- meet regulatory requirements. The only one that
15 would meet it would be for it to go into your Subtitle
16 C ICDF or whatever it's called.

17 MR. O'NEILL: Right. The small sites -- we
18 talked earlier about five soil sites. And the smaller
19 soil sites, the ones that contain other than rad,
20 certainly would have to go to a soil repository. The
21 only one that we're talking about processing through
22 the soil sorter is rad only. That's the only one --
23 only materials that apply to that. The soil sorter
24 only sorts for rad. Okay. And that's the vast volume
25 of material that we have, the wind blown contamination

1 from SL-1. And that's where we hope that implementing
2 this technology will give us a volume reduction and
3 hence reduce our costs.

4 Did that answer your question?

5 AUDIENCE MEMBER: Well, not really. Because
6 you can appreciate that this gets to be pretty
7 confusing for the general public to try to sort out
8 what's in these plans. I mean, you're putting stuff on
9 the table that would be illegal if you tried to
10 implement it. And yet you're not saying clearly --

11 MR. O'NEILL: You lost me on what would be
12 illegal.

13 AUDIENCE MEMBER: I think I can clarify. The
14 comment that he made was we're dealing with mixed low
15 level waste. And that is not the case for these
16 contaminated soil sites, which are the alternatives
17 he's talking about right now for the five contaminated
18 soil sites. It is true we have some low levels of
19 radioactivity and we do have some metals --

20 AUDIENCE MEMBER: You've got heavy metals in
21 there that would violate the land disposal
22 restrictions.

23 AUDIENCE MEMBER: No. The concentrations are
24 low and are not classified as mixed waste.

25 AUDIENCE MEMBER: They're below the hazard

1 waste limits for those particular areas, those
2 particular contaminants. So they are present, but they
3 are not above the requisite limits that would make them
4 a hazardous waste.

5 MR. O'NEILL: You'll notice --

6 AUDIENCE MEMBER: Fourteen hundred and thirty
7 milligrams per kilogram. I mean, that's well over for
8 lead. I mean, I haven't gone through and tried to look
9 at that part of it, but --

10 AUDIENCE MEMBER: But the metal -- I have to
11 look at the site. I'm not sure that that's --

12 AUDIENCE MEMBER: I have the --

13 AUDIENCE MEMBER: If that's the ARA-25 Site,
14 the answer is correct, that is probably higher than the
15 requisite limit. We expect that that material will be
16 sorted and disposed of differently than what will the
17 majority of the low level waste. Although we're
18 talking approximately fifty thousand cubic yards. And
19 that's a very small volume of about seventy cubic
20 yards.

21 AUDIENCE MEMBER: Well, the thing is that
22 this plan sort of doesn't separate out what you just
23 said. I mean, it's not in the plan. If you read the
24 plan, all the soils are going to go --

25 AUDIENCE MEMBER: To an appropriate facility.

1 AUDIENCE MEMBER: -- to either the ICDF or
2 you're offering these other options of excavation and
3 consolidation, another Warm Waste Pond type of
4 scenario, you know, which itself is illegal. But the
5 point is that there is -- you're not making any
6 distinction. And this is the only thing that we've got
7 to go by, basically, between these different soil
8 sites.

9 And the thing is is that you have a
10 responsibility to put options on the table that will
11 meet all your errors and not put anything on -- you can
12 mention that this is something that we'd like to do,
13 but it won't meet this or that error.

14 MR. O'NEILL: And all of the alternatives
15 that were --

16 AUDIENCE MEMBER: And you do mention that a
17 couple of times.

18 MR. O'NEILL: All the alternatives that were
19 evaluated in that proposed plan were evaluated because
20 they met threshold criteria. And you know, we can look
21 further at the details, but each of the alternatives
22 that we evaluated further without mentioning in
23 description were evaluated because they met the
24 threshold criteria.

25 Talk a little bit about the segmented gate

1 system. Currently getting ready to deploy this
2 technology on a demonstration project treatability
3 study. We're going to process a thousand cubic yards
4 of radiologically contaminated soil. Cesium-137 is the
5 contaminant of concern. Based on results of this
6 technology elsewhere we hope to get ninety percent or
7 better volume reduction on those soils. If we can do
8 that it will reduce the overall cost of treating those
9 sites, particularly this site, ARA-23. And by reducing
10 the cost of disposal and by reducing the cost of
11 transportation, particularly if we have to -- if we
12 have to take soil off site to dispose of it.

13 AUDIENCE MEMBER: Is this just the Cesium or
14 is that --

15 MR. O'NEILL: Yeah. That soil that we're
16 processing through that is contaminated with Cesium.

17 AUDIENCE MEMBER: No, the process itself.
18 It's valid for other.

19 MR. O'NEILL: Oh, it could be set up to
20 monitor for a number of different radionuclides. And
21 alpha emitters.

22 MR. O'NEILL: They've done some work with
23 beta emitters as well, but it's strongest impact has
24 been with gamma emitters.

25 Okay. This is a decision tree that you will

1 find in the plan that talks about how we'll take
2 advantage of the information from the treatability
3 study. It also brings in the contingency of an on-site
4 soil repository referred to as the ICDF, the Idaho
5 INEEL CERCLA Disposal Facility. Outlines how we will
6 determine whether or not to sort or, you know, whether
7 the soil would be exposed based on availability of
8 suitable capacity.

9 This slide looks at the various alternatives.
10 Again, Alternative 4 was grouped in with Alternative 5.
11 Basically if the soil sorting technology does not prove
12 effective we won't sort. We will just dispose directly
13 and 5 becomes 4. So for simplicity of presentation, we
14 reduced the number. This line down here is an attempt
15 to look at the benefit at various degrees of efficiency
16 on a soil sorter. Zero percent really means we do not
17 process, we just dispose of directly. The fifty
18 percent is highlighted because that was the
19 conservative assumptions we used when we originally set
20 forth in developing our feasibility study. We did look
21 at, in less depth, likely cost if we get a ninety
22 percent volume reduction. And we'll know more by the
23 end of June whether or not this technology is going to
24 help us or not.

25 The next site is the sanitary waste system.

1 The sludge, as mentioned before, was removed from the
2 septic tanks back in '96. All that remains is the
3 septic tanks, the piping and the seepage pit. There is
4 some sludge at the bottom of the seepage pit.
5 Approximately two yards of material that would be
6 likely taken to the work facility for incineration.
7 Piping and the tank would be decontaminated and
8 disposed on site. And the concrete block that
9 comprises the seepage pit would likely go outside the
10 waste disposal facility. We would like to be able to
11 decontaminate that.

12 Other options we looked at as opposed to
13 thermal treatments, using chemical stabilization. It
14 would require some development work and it would be
15 more expensive than thermal treatment. So we did not
16 go any further with that.

17 Another option would be In Situ
18 Stabilization, meaning we fill the seepage pit and
19 tanks with soil and groundfill and grout and leave the
20 material in place.

21 And the preferred alternative has several
22 advantages. One is cost. The other is that all the
23 material is removed from the environment and disposed
24 of in a suitable repository. Removing the further risk
25 from the environment, like 5.

1 The next one is our radionuclide tank site.
2 Again, this has not been a release, but a release to
3 the environment would be unacceptable. The soils that
4 surround that tank that have all been mentioned are
5 contaminated with Cesium. Those soils would be treated
6 with the other soil sites.

7 We looked at options for vitrifying that tank
8 in place. We looked at vitrifying that tank up at TAN,
9 because they are looking at -- TAN, Test Area North.
10 They are looking at in situ vitrification up there. I
11 thought it might be a nice option to consider doing
12 ours as well.

13 Another option is remove the waste from the
14 tank, take it up and place it in one of the tanks at
15 TAN and treat it there. While we believe that
16 technology would destroy the organics and would
17 immobilize the radionuclides, it has not been
18 demonstrated on tanks with PCBs, and hence compliance
19 would have to be demonstrated, the effectiveness of the
20 treatment would have to be demonstrated. So some post
21 treatment monitoring and sampling would have to be
22 done.

23 Our preferred alternative is to remove that
24 waste, to remove the tank and the waste, take the waste
25 to the advanced mixed waste treatment facility, which

1 is being designed and constructed currently, and to
2 decon the tank and the piping and dispose of it
3 suitably as well. It's likely that the residuals from
4 the thermal treatment would have to go off site.

5 This next option was just off site disposal
6 versus on site. And the last two use a stabilization
7 -- would use a stabilization technology as opposed to
8 thermal treatment. That also would take some
9 treatability studies, some demonstration, because of
10 the radiological nature of the tank and the
11 contamination. And it would be very expensive studies.
12 And since we believe the thermal treatment would be
13 suitable and available, that ranks out as our preferred
14 alternative.

15 AUDIENCE MEMBER: I have a question on where
16 does it -- preferred alternative -- where is the
17 designated implant with the tank? Is it --

18 MR. O'NEILL: The tank --

19 AUDIENCE MEMBER: -- the SDA or what?

20 MR. O'NEILL: If we can effectively decon
21 that tank, it would likely be disposed of at the RWMC.

22 AUDIENCE MEMBER: At the where?

23 MR. O'NEILL: At the radioactive waste.

24 AUDIENCE MEMBER: In the subservice disposal
25 area?

1 MR. O'NEILL: Right.

2 AUDIENCE MEMBER: As debris. In other words,
3 the tank would be cut off and disposed of at the RWMC.

4 AUDIENCE MEMBER: Could we also look at that
5 possibly of that going to ICDF?

6 AUDIENCE MEMBER: The tank itself?

7 AUDIENCE MEMBER: Because it wouldn't need
8 to; is that --

9 AUDIENCE MEMBER: No, it wouldn't. It's
10 entirely possible we could decon it sufficiently and
11 scrap it, send it to the bulky wasteland fill.

12 AUDIENCE MEMBER: Thank you.

13 MR. O'NEILL: You can see that our preferred
14 alternative doesn't rank out as the least expensive,
15 but there are issues with taking that waste to TAN,
16 placing it back in the ground and treating it,
17 regulatory issues that would make it difficult to
18 implement. And you can see that implementability on
19 those options are considered low.

20 Relatively small site to be able to remove
21 the tank, the vault and any piping associated with it
22 from the environment would be a simple -- simple --
23 relatively simple fix; would remove the threat of that
24 contamination from the environment.

25 So in summary, we looked at fifty-five

1 potential release sites. Forty-eight of them were
2 determined to require no further action. Seven sites
3 were determined to pose an unacceptable risk to humans
4 or the environment. Two of them are specifically the
5 ecological sites only. The others are a mix of the --
6 their human health or human health and ecological.

7 Our preferred alternatives as proposed could
8 cost a combined total of twenty-six million dollars.
9 If, however, the volume reduction gained on the soil
10 sorter is where we would like to be upwards of ninety
11 percent, we could save five million on that total. And
12 the direct disposal cost would likely win out if we
13 can't beat those numbers. And it would come in around
14 that range as well.

15 Public involvement is what you're here for,
16 it's what we're here for, to hear what -- to let you
17 know what we're thinking and for you to let us know
18 what you're thinking. Our comment period began May
19 10th and it was scheduled to complete on June 9th.
20 We'll begin developing our record of decision. We hope
21 to have agreement on that this fall. Immediately
22 following that we will begin our remedial design and
23 would hope to be in the field in 2001 and complete
24 these activities sometime in 2003.

25 With that, I turn the meeting back over to

1 Erik. Thank you.

2 MR. SIMPSON: Thanks. Okay. There were some
3 questions during the presentation. Any other questions
4 now?

5 AUDIENCE MEMBER: Could somebody just give me
6 a quick explanation of the soil sorter thing.

7 AUDIENCE MEMBER: I'll give it a shot. You
8 might have seen some pictures there. Basically, it's a
9 conveyance system, conveyer belt with a series of
10 detectors, radiological detectors, soedionymied, couple
11 rows of those detectors. The soil is run through a
12 screen to get rid of large rocks and things. And it is
13 leveled to less than two inches on the belt, passed
14 below the detectors which survey -- when they find a
15 material that exceeds the set point it sends a signal
16 to a series of gates that reach out and grab the soil
17 in front of, behind and to the side of that detected
18 element and diverts it to a dirty pile. The rest of
19 the soil going to a clean pile.

20 AUDIENCE MEMBER: You might also discuss some
21 of the results that they've had, some of the various
22 facilities.

23 AUDIENCE MEMBER: We've employed this at a
24 number of DOE sites, much for demonstration, some
25 support actual cleanup. Particularly worked well down

1 at San Dia. They had ninety-nine point five percent
2 volume reduction on depleted uranium. But their
3 particles were very discreet.

4 Down at Nevada the nuclear test site, where
5 they basically blew up nuclear weapons, the stuff was
6 very, very finely divided. And whether it was through
7 the way that they excavated or just the nature of the
8 material, they did not get separation that could beat
9 their twenty-five dollar a cubic yards disposal cost,
10 which is tough to beat.

11 Also, it's been deployed out at Otfernauld.
12 I think they're up in the ninety percent range as well.

13 AUDIENCE MEMBER: Johnston Atol --

14 AUDIENCE MEMBER: Johnston Atol, they
15 processed two hundred fifty thousand cubic yards.

16 AUDIENCE MEMBER: They were well into the
17 ninety percent volume reduction range there.

18 AUDIENCE MEMBER: How about also pointing out
19 that this appointment that is funded by DCD -- or DOE
20 headquarters in Washington D.C. under a grant of
21 technology development program that was looking for
22 candidate sites to apply this and try it. And the
23 moneys were available competitively nationwide, the
24 application was placed to try it at this site, and
25 awarded to DUEID. And the treatability study on this

1 demonstration, from a practical standpoint, we have
2 nothing to lose, and perhaps something to gain by
3 trying it at this site and seeing if it works on a
4 contingent basis.

5 So first of all, we have to make sure it will
6 work there. This looks like a site that was made to
7 order for this technology. It doesn't work everywhere.
8 And then to make sure that it indeed offers some cost
9 benefits in addition to volume reduction, in which case
10 we will utilize it.

11 So like I said, we have nothing to lose by
12 bringing it in and trying it, from the local
13 perspective.

14 Chuck, did you have any others questions?

15 AUDIENCE MEMBER: Well, it seemed that there
16 would be a lot of room for problem areas, particularly
17 with alpha emitters, unless you got that stuff right
18 down to a granular layer on the conveyer belt and it
19 went real slow, because you can -- it's not so much of
20 a problem with gamma emitters, that's a lot easier to
21 pick up, obviously. But alpha emitters would be a lot
22 more problematic.

23 AUDIENCE MEMBER: Well --

24 AUDIENCE MEMBER: The characteristic
25 contaminant, of course, that we will be setting the

1 technology for is the cesium-137. I'm not sure what
2 our set point is yet, but it's well below --

3 AUDIENCE MEMBER: It's like twelve point one
4 picocuries per gram with a cleanup goal of point three.
5 So it's about half.

6 AUDIENCE MEMBER: I think it can be used for
7 alpha emitters as long as they're accompanied with
8 something that's more readily detectable. I think
9 that's what we --

10 AUDIENCE MEMBER: Or if the specific isotope
11 also has a gamma component.

12 AUDIENCE MEMBER: Part of the problem with
13 alpha is you've got to remember this material runs
14 under a radiation detector. Just about anything will
15 stop alpha, where gamma you get a much better signature
16 and a much deeper response. And that's why it's been
17 real effective with depleted uranium and hopefully
18 cesium-137 at a couple different sites.

19 AUDIENCE MEMBER: Yeah. I saw a PBS special
20 on the Johnston Atol, and it was characterized pretty
21 good virtually as an absolute disaster that didn't
22 work.

23 AUDIENCE MEMBER: For this treatment system
24 or --

25 AUDIENCE MEMBER: It's funny. They're still

1 using it, they have four units that have been operating
2 now for almost five full years and they've ordered a
3 couple new units.

4 AUDIENCE MEMBER: Well, maybe they changed
5 the process. Didn't you say ninety percent?

6 AUDIENCE MEMBER: On Johnston Atol, I don't
7 remember the exact number, but it was up in the ninety
8 percent, as I recall. And again, it depends. If you
9 have a very discrete particle, particularly with gamma,
10 the system works very well. It has trouble with play
11 balls, you know, something more than where you're
12 marking with the actual soil characteristics.

13 Our particular case works a little more of a
14 sandy soil, particularly in the top couple of inches
15 with discrete particles that radiation technicians used
16 to actually go out and isolate and literally particle
17 pick with tweezers. We feel it will work well. But
18 the jury is still out. We won't know until June.

19 AUDIENCE MEMBER: Do you prep the material
20 before it goes through the --

21 AUDIENCE MEMBER: No. In fact, they
22 recommend that you handle it very little, the less
23 handling the better. The more you handle it, the more
24 homogenized it is. And the way the process is actually
25 set up, it defaults to the dirty pile. So they

1 actually prefer that you try and control -- part of our
2 treatability study will be to look at different methods
3 of excavation to keep from homogenizing the soil. When
4 in doubt, the material goes to the dirty pile.

5 AUDIENCE MEMBER: Yeah. I misspoke.
6 Actually the gates reach out and collect the clean
7 material; isn't that correct?

8 AUDIENCE MEMBER: Right.

9 AUDIENCE MEMBER: And that's an operational
10 decision they made for the way the system seemed to
11 function better. There is some possible conditioning
12 that would be in the moisture content?

13 AUDIENCE MEMBER: Well, moisture content and
14 removal of the oversized. They typically put a grizzly
15 on the top of it to remove the oversized. And then
16 that material is either considered dirty or there is
17 some other field screening method and/or analytical
18 method used to determine the status of that particular
19 waste group.

20 MR. SIMPSON: Others? Other questions.

21 Go ahead, Chuck.

22 AUDIENCE MEMBER: Well, one of the -- one of
23 the undones right now is the -- this new ICDF disposal
24 site, this Subtitle C hazardous mixed -- hazardous
25 waste disposal site. And from our perspective, I mean,

1 we're tickled to death that there seems to be a
2 commitment to finally build one of these things.
3 Certainly we've been very critical in the past years
4 all the way up, you know, that it really hasn't been
5 the kind of commitment to meet regulatory requirements
6 in terms of the disposal of mixed low level waste.

7 The problem is, from our perspective, it
8 doesn't look like there is going to be a public process
9 of where, you know, there is going to be an opportunity
10 to have an open discussion about where to build it.

11 MR. SIMPSON: I'll let Scott address that.

12 AUDIENCE MEMBER: And you've gotten all our
13 written comments about those issues. And it doesn't
14 seem to be the kind of commitment on DOE's part to
15 provide the kind of additional funding for the
16 hydrology studies through the MOU with the USGS to
17 expand on the 1989 hundred year modeling of a hundred
18 year flood on the site. And the modeling that was done
19 only did the median flow rate, didn't model the maximum
20 flow that is possible.

21 And even with the median flow, the north end
22 of the chem plant would be under water. And it's a
23 difference between eleven thousand something six
24 hundred cubic feet per second and -- I think they
25 modeled seven thousand something as a mean.

1 MR. RENO: Let me -- you got about three questions
2 there. Let me hit those before you go on so I can keep
3 track. The first one was on public involvement. And I
4 think the agencies realize that there is a -- there has
5 been quite a bit of public interest there in the
6 proposed facility. And I don't think we make any
7 specific commitments tonight -- it's something that we
8 have to work with management -- but if there is such a
9 facility, then I think we're going to look at having
10 some workshops -- briefings probably, at a minimum, to
11 interested parties, and probably some workshops to go
12 over some of the design issues and then involvement of
13 the waste acceptance criteria.

14 But I would like to emphasize that first of
15 all, there had not yet been a decision made to build
16 this facility. It's pending. And there has been some
17 members of the public who have opposed the idea of
18 constructing it on site. And so we'll see what happens
19 in the WAG3 record decision.

20 But if there is one, then we will look at
21 trying to incorporate interested stakeholders into the
22 process and hearing their concerns as we cite it,
23 design it and develop the waste acceptance criteria.

24 AUDIENCE MEMBER: If I can interject real
25 quick on behalf of this gentleman, because I think

1 everybody else is pretty familiar with what's going on.
2 The disposal facility we're talking about would be
3 developed under another waste area group known as Waste
4 Area Group 3. We would only take beneficial effects if
5 it exists or not. We're not planning to cite one under
6 this action. Thanks.

7 AUDIENCE MEMBER: Now on the last issue, our
8 rain issue on some of the flooding concerns, I know I
9 speak for the state that we share some of those
10 concerns. And I believe that the DOE and EPA also
11 recognize that the existing flood analysis that has
12 been done is conflicting in some of the reports, and
13 that there were no definitive answers on where the
14 flood plain a hundred years, five hundred year, maybe
15 needs to be arrived at. As it might relate to siting
16 this facility in the vicinity of the chem plant, I
17 think we believe that engineering controls to address
18 any potential flood plain issues are fairly easy to
19 accommodate. So --

20 AUDIENCE MEMBER: Well, in other words,
21 you're sticking by what we talked about on the other
22 conversations on the same topic that you're going to --
23 you're going to try to rely on liners to insulate to
24 protect the waste from a flood. And --

25 AUDIENCE MEMBER: That.

1 AUDIENCE MEMBER: -- the thing is, you got to
2 remember what those liners --

3 AUDIENCE MEMBER: You're talking about under
4 flow. Yeah. I was specifically referring to berms.
5 But you're talking about under flow and berms. And the
6 liners should -- they're designed to prevent water from
7 infiltrating and --

8 AUDIENCE MEMBER: No, they're not. You know
9 what they're designed to do? They're designed to stop
10 any small amount of moisture that squeaks by the
11 impervious top and keep it from migrating out. That's
12 what those liners are designed to do. And that is --
13 you're talking about no hydraulic lift there, no
14 pressure, virtually. And you're talking about a very
15 minor amount of water, assuming that the cap works.
16 You know, you're talking about a whole different kind
17 of scenarios. And I find it real hard to accept that
18 perspective.

19 MR. RENO: I respect that, Chuck. And you
20 are correct in that the bottom liners which are being
21 proposed at this facility, one of clay and perhaps one
22 synthetic, they need to be less permeable than the top
23 layer. And you don't have the bathtub effect and you
24 don't develop that with it. However, we would not
25 expect a flooding event to be present for months at a

1 time and to penetrate the cap. But it is a design
2 factor that we will need to consider and recognize.
3 And we hope to come up with a plan soon that we can
4 incorporate stakeholders' concerns in the process
5 before we can make final decisions on these things.

6 AUDIENCE MEMBER: Another argument for
7 putting it there at the chem plant where the SPERT
8 plants are that I heard yesterday, I think -- Kathleen
9 and I were chitchatting. And she was saying something
10 to the effect that, while it's already contaminated
11 from wind blown whatever plus the SPERT plans are
12 contaminated, why go find a nice clean place and then
13 mess that up too. You know, as an argument for
14 weighing, Pierre's offered the same kind of argument.
15 And I was reading recently Larry Craig's questions to
16 the department. And he put out a very, very
17 interesting rebuttal to that kind of perspective. He
18 says, you know, how are we going to know whether the
19 thing is working or not if you're over the top of an
20 existing contaminated site? It's like pretty clear
21 reasoning there. You'd have no way of knowing whether
22 -- if you had groundwater contamination under that or
23 whether it was residual from the chem plant or from the
24 SPERT ponds or anything else like that. And DOE could
25 go on forever saying it's not coming from the new

1 disposal site. It's residual stuff that was there
2 before.

3 AUDIENCE MEMBER: Well, part of the argument
4 would be that I would have to characterize the existing
5 pond, which that particular waste stream would have its
6 own signature.

7 Now assuming you were disposing of material
8 that had the exact same signature, your argument would
9 hold water. Assuming that the signatures were somewhat
10 different, then you would be able to tell. But your
11 point is well taken.

12 AUDIENCE MEMBER: So you can actually
13 distinguish between strontium that came from ARA and
14 strontium that came from the chem plant?

15 AUDIENCE MEMBER: No. What I am saying --
16 signature as far as the concentrations. If you have a
17 good characterization of your existing area of where
18 you build your pond, it gives you a pretty good feel
19 for what you have -- you know, where you were at for a
20 baseline prior to doing it. But your point is well
21 taken.

22 MR. RENO: It is well taken, Chuck. And I
23 think our objective is -- although there would be water
24 train of the plane off, our objective would have been
25 to have an early leak detection before any contaminants

1 ever reached the aquifer. And that would consist of
2 monitors between the layers of the bottom liner and
3 beneath the facility itself to ensure that any leach
4 aid or no leach aid from the landfill was going to have
5 the potential impact.

6 AUDIENCE MEMBER: Well, that's a given.
7 That's a requirement that you would -- you don't have a
8 choice about that part.

9 MR. RENO: But that's a valid concern and
10 another issue that needs to be addressed in the
11 monitoring plan and the design issues for the facility.
12 We believe that we can adequately address those. We're
13 not in disagreement with you. And also with siting.

14 AUDIENCE MEMBER: Yeah. Apparently a lot of
15 the politics that are driving some of those
16 perspectives are trying to protect the private owned
17 EnviroCare and Utah's interest in getting Idaho's
18 waste.

19 AUDIENCE MEMBER: No comment. Follow the
20 money.

21 MR. SIMPSON: Chuck, do you have any other
22 questions?

23 Let's come back at eight thirty and then
24 we'll have the public comment session. It's about
25 seven minutes.

1 (Whereupon, the hearing was in recess at
2 8:23 p.m. and subsequently reconvened at 8:42 p.m.; and
3 the following proceedings were had and entered of
4 record:)

5 AUDIENCE MEMBER: My name is Chuck Broschious,
6 B-R-O-S-C-I-O-U-S. I'm the Executive Director for the
7 Environmental Defense Institute in Troy, Idaho. The
8 comments that I have on this proposed plan revolve
9 around questions of what the -- what the waste category
10 for the radioactive waste tank actually is. There
11 seems to be some different data sets that -- one data
12 set says it's a mixed transuranic waste, the other data
13 set says that it's not.

14 I submitted for the record copies of the
15 Final Work Plan for Waste Area Group 5, Operable Unit
16 5-12, Comprehensive Remedial Investigation Feasibility
17 Study that says on Page A-8 that the waste in the tank
18 is F listed transuranic waste. And in the same
19 document on Page D-17 the concentration levels easily
20 make the criteria of a hundred nanocuries per gram of
21 transuranic waste. So as far as that -- this document
22 is concerned, it should be listed as transuranic waste.

23 If that is the case, then the alternatives
24 for that particular waste site, this is ARA-16, a
25 number of the alternatives are listed as utilizing in

1 situ vitrification would not be legal, because there is
2 no place on the INEEL site that would qualify as a
3 transuranic -- permanent transuranic waste disposal
4 facility. Matter of fact, there is only one in the
5 country and that's in New Mexico.

6 The -- I have gained commitments from various
7 officials here that they will send me copies of this
8 other sampling data that they claim says that it's
9 mixed low level waste. So I'm anxiously awaiting that.

10 Okay. Where are we here? There was a lot of
11 discussion earlier in the meeting unofficially about
12 where the preliminary remedial goals that are listed in
13 the plan come from. There is some acknowledgment here
14 on Page 12 that they are EPA approved screening levels.
15 But as far as I could tell, in downloading the EPA
16 preliminary remediation goals, they don't match. And
17 it doesn't seem to be any -- any documentation on how
18 those preliminary remediation goals are derived and
19 what basis they're -- they're arrived at.

20 I think if you're going to use them, then you
21 have to make that information available, maybe not
22 referenced where a member of the public can go find out
23 where those -- where those numbers -- where they came
24 from and what justification there is for them.

25 There is a lot of reliance on the eventual

1 construction of the ICDF -- INEEL CERCLA Disposal
2 Facility. The citing of that particular disposal
3 facility needs to be a very public process where the
4 public can have an opportunity to be involved with that
5 decision-making process. It should not be done in any
6 other closed door manner where our concerns about the
7 flood zone areas, as far as we're concerned, should be
8 excluded -- exclusionary parts of the site where
9 disposal facility -- new disposal facilities will not
10 be allowed to be constructed.

11 That's all I can think of offhand. That's
12 it.

13 MR. SIMPSON: Okay. Thank you, Chuck.

14 Sir, do you have any comments?

15 AUDIENCE MEMBER: No, no.

16 MR. SIMPSON: Okay. Just for the record,
17 comments made here tonight will be responded to in the
18 responsiveness summary section of the record of
19 decision.

20 Also I just wanted to remind people that the
21 comment period remains open on this project until June
22 9th. And the next time that we'll hold public meetings
23 will be sometime this summer, either July or August
24 when we will discuss the Central Facilities Area
25 project involving contaminated soils. And there is an

1 interim action proposed to address those contaminated
2 soils.

3 With that, thanks for coming tonight and good
4 night.

C E R T I F I C A T E

STATE OF IDAHO)
 : SS.
 County of Nez Perce)

I, Jessica S. Berke, CSR, Freelance Court Reporter and Notary Public for the State of Idaho, License No. 680, and the State of Washington, License No. 299-06 BE-RK-EJ-S318LL, residing in Lewiston, Idaho, do hereby certify:

That I was duly authorized to and did report the hearing in the above-entitled cause;

That the foregoing pages of this hearing constitute a true and accurate transcription of my stenotype notes of the testimony of said witness.

I further certify that I am not an attorney nor counsel of any of the parties; nor a relative or employee of any attorney or counsel connected with the action, nor financially interested in the action.

IN WITNESS WHEREOF, I have hereunto set my hand and seal on this 12th day of July , 1999.

Jessica S Berke
